# Daily Pattern recognition of Harmonic Currents of Residential Low Voltage Networks

Authors: Ana Maria Blanco, Jan Meyer,  
Peter Schegner, Andres Pavas

Institutions: Technische Universität Dresden and  
Universidad Nacional de Colombia

# Contents

**I. Introduction**

**II. Distance and similarity measures**

**III. Measurement campaign**

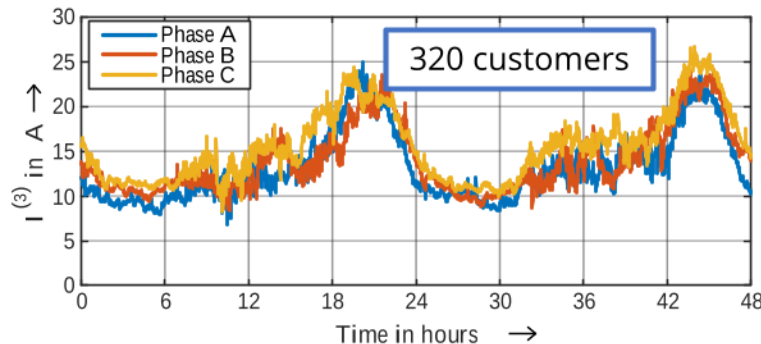

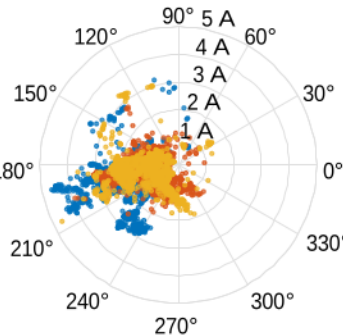

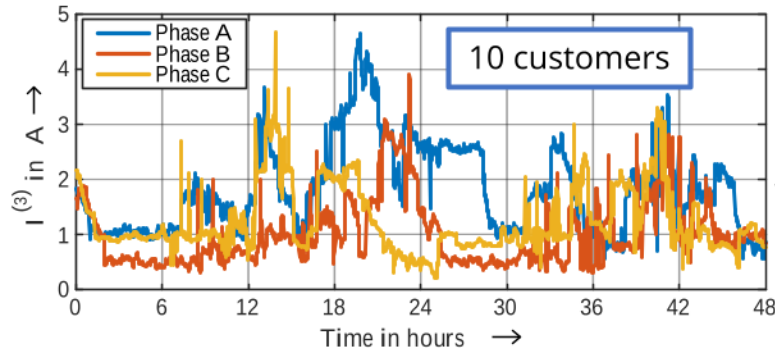

**IV. Application of distance and similarity measures**

**V. Conclusions**

**VI. Questions**

# I. Introduction

- Harmonic emission characteristic depends on the number of aggregate customers

Amount of customers

- “smoother” magnitude
- Prevailing direction of phase angles

# I. Introduction

- Daily pattern of harmonic magnitudes and phase angles?
  - Which harmonic orders?
  - Similar pattern for different networks?
- Modeling using time-series?
- Analyze the daily pattern characteristics of the harmonic currents in typical residential low-voltage networks.
  - Application of distance and similarity measures.
  - Measurements of different residential networks.

## II. Distance and similarity measures

### 1. Distance Measures:

- Euclidean distance in time domain
- Minkowski distance in time domain
- Euclidean distance in frequency domain

### 2. Similarity measures:

- Cosine measure
- Pearson's correlation coefficient

$$DM_E = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} = 15.18$$

$$SM_P = \frac{\sum_{i=1}^n (x_i - \mu_x)(y_i - \mu_y)}{\sqrt{\sum_{i=1}^n (x_i - \mu_x)^2 \sum_{i=1}^n (y_i - \mu_y)^2}} = 1$$

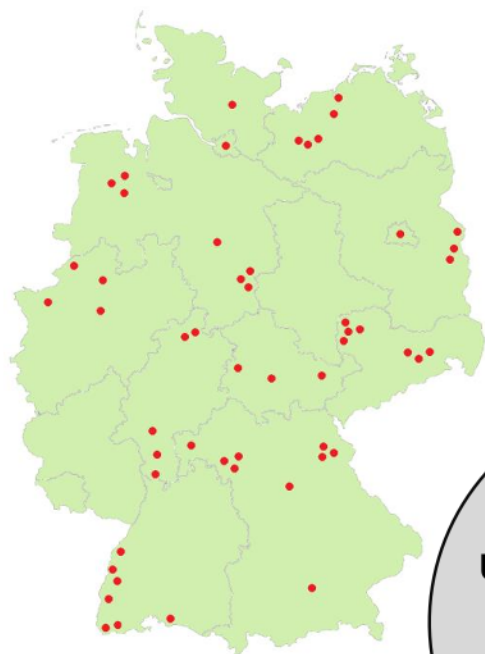

## II. Distance and similarity measures

Case	Distance			Similarity	
	$DM_E$	$DM_{M\infty}$	$DM_{FFT}$	$SM_C$	$SM_P$
1	15.18	0.4	0.4	0.966	1
2	2.45	0.14	0.082	0.995	0.95
3	6.57	0.29	0.245	0.944	0

### III. Measurement campaign

- 37 residential low-voltage networks
- Minimum 80% of residential customers
- Low penetration of PV systems ( $P_{G\text{TOT}} < 0.1 \cdot S_{RT}$ )
- Minimum 1 week of measurements in winter
- Holidays were excluded
- Magnitude and phase angle of current harmonics
- Electrical characteristics of the network, climate and social conditions

# IV. Application of distance and similarity measures

- Current magnitudes are normalized (min-max normalization) and smoothed (moving average, window of 10 minutes).
- Method is applied to phase components and sequence components.
- Thresholds for the distance and similarity measures obtained based on the fundamental and third harmonic currents.

# IV. Application of distance and similarity measures

## *Similarity for single sites*

- $DM_E$  and  $SM_P$  measures were calculated between the daily curves of each site and each phase.
- Harmonic currents of a site have a daily pattern only if at least 80% of the days are similar between them (80% of the days have good or acceptable  $\overline{DM}_{E,i}$  and  $\overline{SM}_{P,i}$ ).

# IV. Application of distance and similarity measures

## *Similarity between sites*

- $\overline{DM}_{E,i}$  and  $\overline{SM}_{P,i}$  were calculated between all daily curves of the balanced component of harmonic current magnitudes of sites with clear daily patterns.

	Harmonic order							
	1	3	5	7	9	11	13	15
Percentage of days	100	100	97.4	93.3	97.6	84.5	81.7	73.9

**Daily patterns ✓**  
**Time-series modeling ✓**

## V. Conclusions

- Only the fundamental, 3<sup>rd</sup> and 9<sup>th</sup> harmonic magnitudes show a clear daily pattern during the whole week in more than 80% of the measured residential networks.
- For other harmonic orders the randomness of the harmonic magnitudes is higher and a daily pattern is not recognizable for all the networks.
- If the balanced component of the harmonic currents is used instead of the phase currents, and if only workdays are considered, the results improve considerably.
- Daily patterns of the harmonic currentmagnitudes of almost all residential networks (>80% of the networks) have very similar characteristics.
- Harmonic phase angles do not show a clear daily pattern.

# Thank you for your attention!
