## ABSTRACT

Anurophagy represents a small percentage of anurans' diet, however, the observation of this behavior is frequent and well-documented. Herein we reported two events of anurophagy of *Leptodactylus macrosternum* preying a newly metamorphosed *Physalaemus nattereri* and an adult *Boana punctata*, both in the municipality of Dois Irmãos do Buriti, Mato Grosso do Sul state, Western Brazil. Additionally, we summarized literature records of anurophagy in *Leptodactylus*. We found 99 records of anurophagy in different stages of development. *Physalaemus nattereri* and *Boana punctata* have never been reported as prey for *Leptodactylus* and this predation might be due to a combination of abundance and the high call activity during the breeding season. Anurophagy in *Leptodactylus* has more records for large-sized species, even in the larvae stage. Anurophagy occurrence in leptodactylids may be related to the size of the predator, habitat, and area diversity since more complex and diverse environments tend to present more anurophagy events.

**Keywords:** Batracophagy, diet, predation.

## RESUMEN

La anurofagia representa un pequeño porcentaje de la dieta de los anuros, sin embargo, es un comportamiento común y bien documentado. Reportamos aquí dos eventos de anurofagia de *Leptodactylus macrosternum* depredando un juvenil metamorfo de *Physalaemus nattereri* y un adulto de *Boana punctata*, ambos eventos en el municipio de Dois Irmãos do Buriti, estado de Mato Grosso del Sur, Brasil. Adicionalmente, presentamos una revisión de los eventos de anurofagia del género *Leptodactylus*. Encontramos en total 99 registros de diferentes estados de desarrollo. *Physalaemus nattereri* y *Boana punctata* no habían sido reportadas como presas de *Leptodactylus*. Estas depredaciones pueden deberse a una combinación de la abundancia y la alta actividad de canto durante la reproducción. La anurofagia en leptodactílidos ha sido registrada mayormente en especies de gran tamaño, incluyendo en estados larvales. La ocurrencia de la anurofagia puede ser predicha por el tamaño del depredador, el hábitat y la diversidad del área, siendo que ambientes más complejos y de mayor diversidad tienden a presentar más eventos de anurofagia.

**Palabras clave.** Batracofagia, dieta, depredación.

Anurans play an important role in food webs in different habitats (Duellman and Trueb 1994). In the Neotropical region, they feed mainly on arthropods, and they are predated by fish, mammals, birds, reptiles, and invertebrates (Andrade et al. 2012, Aoki and Landgref-Filho 2013, Oliveira et al. 2014, Cortés-Gómez et al. 2015, Ferreira et al. 2017, Folt and Lapinski 2017, Ceron et al. 2019, Landgref-Filho et al. 2019, Cruz-Sáenz et al. 2020). Eventually, anurans can eat other frogs (i.e., anurophagy), and although this behavior represents a small percentage of anurans' diet, these events are well-documented (Toledo et al. 2007, Loebmann 2013, Oda et al. 2019, Caicedo-Martínez et al. 2021). Most anurans are known by their generalist diet, and their prey sizes may be related to the tongue and the mouth shape (Emerson 1985). For those reasons not only, the size is related to anurophagy, but also the skull shape and the habitat, especially in environments with high anuran abundance (Emerson 1985, Scott and Aquino 2005, Measey et al. 2015). Among Neotropical anurans, reports on anurophagy events in *Leptodactylus* are frequent (Sanabria et al. 2005, Toledo et al. 2007, Ávila-López et al. 2012, Sierra-Rueda and Acosta-Ortiz 2020). *Leptodactylus macrosternum* Miranda-Ribeiro, 1926, commonly called butter frog, is a large species (48.7–98.9 mm snout-vent length [SVL]) belonging to the *L. latrans* group (Magalhães et al. 2020). *Leptodactylus macrosternum* has a wide distribution in South America, from Santa Fé, Argentina, to northern Brazil and the Guiana Shield; also, it has been recorded in Trinidad and Tobago (Magalhães et al. 2020, Frost 2021).

*Leptodactylus macrosternum* reproductive activity occurs mainly during the rainy season (Prado et al. 2000, Camurugi et al. 2017). It is a generalist species with a foraging strategy between sit-and-wait and active search; its diet includes mainly coleopterans (Schaefer et al. 2006, Camurugi et al. 2017). Although anurophagy is well known for *Leptodactylus* species, most of the records are solely based on anecdotal observation, with the preyed anurans identified only to the order level (i.e., Anura) (e.g., Gallardo 1964, Maneyro et al. 2004, Solé et al. 2009, Camurugi et al. 2017).

Prey identification is fundamental to understanding trophic interactions (Ceron et al. 2020a), the role of anurans as energy and protein sources to other animals (Cortés-Gómez et al. 2015), the role of predators as regulators, and the possible drivers of anurophagy (Measey et al. 2015). Given the lack of specific records, herein we report two new anurophagy events of *Leptodactylus macrosternum* and provide a list of anurophagy cases for the genus *Leptodactylus*.

Both new records occurred at the edge of a permanent pond at Estância Crioula Farm, located at Dois Irmãos do Buriti municipality, Mato Grosso do Sul state, Western Brazil ( $20^{\circ} 32' 07''$  South,  $55^{\circ} 33' 00''$  West). All specimens were collected under SISBIO license (SISBIO 49080-5), killed with lidocaine (5 %), fixed in 10 % formalin, preserved in 70 % Ethanol, and housed at Coleção Zoológica da Uni-

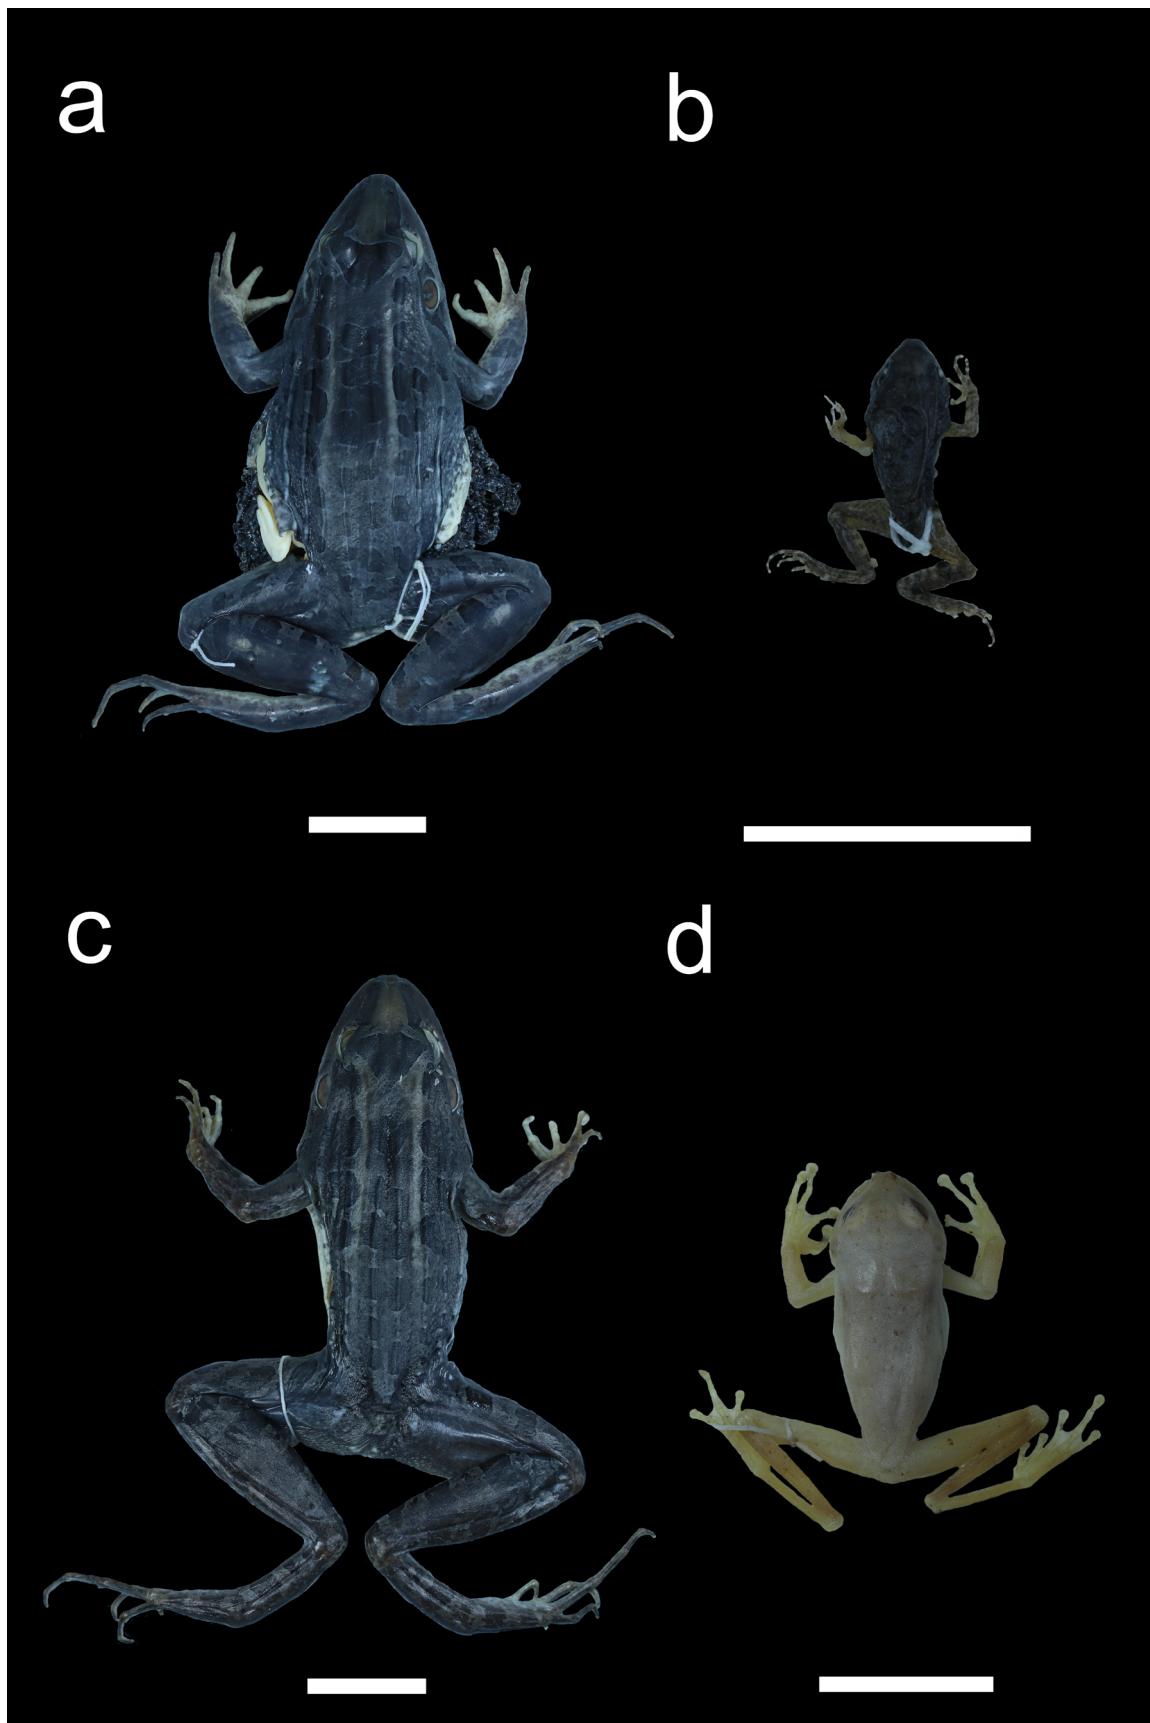

versidade Federal de Mato Grosso do Sul (ZUFMS-AMP). Additionally, to recover a list of anurophagy records by *Leptodactylus* species as predators from literature, we used the following keywords: “*Leptodactylus*”, “Anurophagy”, “Diet”, “Predation” and “Cannibalism” in “Google Scholar”. As a complement, we checked specialized journals such as Herpetological Review and Herpetology Notes, in the “Natural History” section. We included studies of diet, even with unidentified prey. The size category of species follows Haddad *et al.* (2013), who considered species as small (< 3 cm), medium (3 – 10 cm), and large (> 10 cm). We included reports of predation attempts or regurgitations and exclude those that not occurred in nature (e.g., Regnet and Loebmann 2017). When information about the locality and/or photographs allowed a more precise prey and predator identification, we included it (e.g., Faivovich *et al.* 2005, Heyer 2005, Frost *et al.* 2006, Narvaes and Rodrigues 2009, Duellman *et al.* 2016, Magalhães *et al.* 2020; Gazoni *et al.* 2021). Details about species names originally reported by authors are in [Supplementary file 1](#).

Our first report occurred on 11 Nov 2020, around 20:00h, when we collected a female of *L. macrosternum* (SVL= 77.10 mm, ZUFMS-AMP13951, [Fig. 1a](#)) with an anuran leg out of its mouth. After dissection, we identified that the prey was a juvenile of *Physalaemus nattereri* (Steindachner, 1863) (SVL=13.62, ZUFMS-AMP13952, [Fig. 1b](#)). That night we recorded at the same pond the species *Boana raniceps* (Cope, 1862) in calling activity and saw individuals of *Leptodactylus podicipinus* (Cope, 1862) and *L. macrosternum*. The second report occurred at the edge of the same pond. This report occurred on 3 Mar 2021, around 20:00h. During that night *Boana punctata* (Schneider, 1799), *B. raniceps*, *Dendropsophus minutus* (Peters, 1872), and *Pithecopus azureus* (Cope, 1862) were calling; *L. macrosternum* and *Leptodactylus podicipinus* (Cope, 1862) were also observed although no calling behavior was recorded in these species. We observed and handled a female of *L. macrosternum* (SVL=79.21mm, ZUFMS-AMP14659, [Fig. 1c](#)) with an adult of *Boana punctata* (SVL=35.29 mm, ZUFMS-AMP14649, [Fig. 1d](#)) in its mouth. After we stored the *L. macrosternum* in a plastic bag, the *B. punctata* was regurgitated.

We found 66 references reporting events of anurophagy for a total of 99 records (101 including both records described here) ([Table 1](#)). Large-size species represent 64.35 % of the total records, Medium-size species, represent the others 35.65 % and we were not able to find anurophagy in Small-size leptodactylids.

The four-eyed frog, *P. nattereri*, has inguinal macroglands that can be used against predators during deimatic display (Lenzi-Mattos *et al.* 2005). This species has already been reported as prey for other species of *Leptodactylus* (Vaz-Silva *et al.* 2003, França *et al.* 2004), however, in two events, with *L. luctator* (Hudson, 1892), the toxin secreted by *P. nattereri* was efficient to avoid predation (Rodrigues and Filho 2004). In the present report, the preyed individual was a juvenile, newly metamorphosed, which may suggest that this is a less-effective defensive method at this life stage such as occur in *Rhinella arenarum* (Hensel, 1867) (Regueira *et al.* 2016). During the night of the second event of anurophagy reported here, many *B. punctata* were exhibiting calling behavior. This species selects different vegetation strata to call and exhibits territorial behavior, moving 100 cm around the calling site (Brunetti *et al.* 2014). The combination of the high abundance and the increase in calling activity and mobility during the breeding season of these species might result in occasional encounters and subsequent predation of *L. macrosternum* upon *B. punctata*. This is the first report of *Leptodactylus* preying on *B. punctata*.

Although some large frogs, such as bufonids, are negligible predators of anurans (Measey *et al.* 2015), in leptodactylids the majority of anurophagy events are displayed by large-size frogs ([Table 1](#)). In medium size species, *L. macrosternum* represents half of the anurophagy records and it is the largest species of its category (Maximum SVL=9.89cm). Trophic ecology studies are paramount to follow temporal variations and the diversity of interactions (Ceron *et al.* 2020a, 2020b). For that purpose, we need proper identification of both, predator, and prey species. Our literature review on anurophagy by *Leptodactylus* leaps further in the anuran trophic ecology, which includes new records.

**Figure 1.** Individuals from the two anurophagy events reported. **a.** *Leptodactylus macrosternum*, **b.** juvenile of *Physalaemus nattereri* preyed on by the specimen "a", **c.** *L. macrosternum*, **d.** *Boana punctata* found inside the mouth of the specimen "c". Scale bar= 20mm.
